CS 39 Winter 2005 Theory of Computation

## Homework 2 Due Jan 21, 2005

Prof. Amit Chakrabarti Computer Science Department Dartmouth College

Please think carefully about how you are going to organise your answers *before* you begin writing. Make sure your answers are complete, clean, concise and rigorous.

- 1. Let L be the language given by the regular expression  $(ab \cup aab \cup aba)^*$ .
  - 1.1. Design an NFA for L that has no  $\varepsilon$ -transtions and has only 4 states.

[6 points]

- 1.2. Convert the above NFA into a DFA for L by mechanically using the *subset construction* we studied in class. [10 points]
- 1.3. Remove all states that are unreachable from the start state of the resulting DFA, to get a 7-state DFA for L. [3 points]
- 1.4. If you carefully observe this DFA, you will notice two states that can be replaced by a single state. Do this and draw the resulting DFA. Your final DFA should have exactly 6 states. [7 points]
- 2. Construct NFAs equivalent to following regular expressions (your NFAs may have  $\varepsilon$ -transitions):
  - **2.1.**  $10 \cup (0 \cup 11)0*1$

[7 points]

**2.2.**  $((0 \cup 1)(0 \cup 1))^* \cup ((0 \cup 1)(0 \cup 1)(0 \cup 1))^*$ 

[7 points]

- 3. Give regular expressions for the following languages.
  - 3.1.  $\{w \in \{0,1\}^* : w \text{ has three consecutive 0's or three consecutive 1's or both}\}$ .

[7 points]

3.2.  $\{w \in \{0,1\}^* : w \text{ has three consecutive 0's and three consecutive 1's} \}$ .

[7 points]

- 3.3. The set of strings in  $\{0,1\}^*$  with an equal number of 0's and 1's such that no prefix has two more 0's than 1's nor two more 1's than 0's. [10 points]
- 3.4. Let us define a valid floating point number as u.v, where u and v are (finite) strings of decimal digits (0..9) satisfying the following constraints: (the symbol "." between u and v is the decimal point.)
  - i. Neither u nor v may be  $\varepsilon$ .
  - ii. u can be just 0. If u is not 0, u has no leading 0's.
  - iii. v can be just 0. If v is not 0, v has no trailing 0's.

(Thus, for example, 0.0, 231.0 and 5.608 are valid, but 0.00, 05.68, .65, 12. and 4.5100 are not valid.)

Give a regular expression for the set of valid floating point numbers described above. You might want to introduce some notation first to keep your expression small and readable. [10 points]

## Homework 2 Due Jan 21, 2005

Prof. Amit Chakrabarti Computer Science Department Dartmouth College

- 4. Let L be a nonempty language and M an NFA that recognizes L. Prove that M can be converted into an NFA M' which recognizes the same language L and has exactly one accept state. Your proof must describe M' both informally, using plain English, and formally, using mathematical notation. [10 points]
- 5. For a language L over alphabet  $\Sigma$ , define  $\mathrm{HALF}(L) = \{x \in \Sigma^* : \exists y \in \Sigma^* \ (|x| = |y| \ \mathrm{and} \ xy \in L)\}$ . Prove that if L is regular, then so is  $\mathrm{HALF}(L)$ . Your proof  $\mathit{must}$  be formal; proofs not written in a formal mathematical style get very little credit even if they express the right intuition. [16 points]

Hint: Approach 1: Build an NFA. Nondeterministically guess which state the DFA for L will end up in after reading x and nondeterministically guess a y to append to x. Approach 2: Build a DFA. Work forwards and backwards simultaneously and try to meet in the middle.

## **Challenge Problems**

Remember that challenge problems carry no regular credit, but are intended to provide a higher level of challenge for those who want to think further about the theory of computing.

**CP1:** For the language *L* from Problem 1, prove that it is impossible to design a DFA with 5 or fewer states.

**CP2:** For a language L over alphabet  $\Sigma$ , define  $Log(L) = \{x \in \Sigma^* : \exists y \in \Sigma^* \ (|y| = 2^{|x|} \text{ and } xy \in L)\}$ . Prove that if L is regular, then so is Log(L).
