

Please think carefully about how you are going to organise your answers *before* you begin writing. Make sure your answers are complete, clean, concise and rigorous.

1. Let  $L$  be the language over the alphabet  $\{a, b\}$  given by the regular expression  $(ab \cup aab \cup aba)^*$ .
  - 1.1. Design an NFA for  $L$  that has no  $\varepsilon$ -transitions and has only 4 states. [6 points]
  - 1.2. Convert the above NFA into a DFA for  $L$  by mechanically using the *subset construction* we studied in class. [10 points]
  - 1.3. Remove all states that are unreachable from the start state of the resulting DFA, to get a 7-state DFA for  $L$ . [3 points]
  - 1.4. If you carefully observe this DFA, you will notice two states that can be replaced by a single state. Do this and draw the resulting DFA. Your final DFA should have exactly 6 states. [7 points]
2. Construct NFAs equivalent to following regular expressions (your NFAs may have  $\varepsilon$ -transitions):
  - 2.1.  $10 \cup (0 \cup 11)0^*1$  [7 points]
  - 2.2.  $((0 \cup 1)(0 \cup 1))^* \cup ((0 \cup 1)(0 \cup 1)(0 \cup 1))^*$  [7 points]
3. Give regular expressions for the following languages.
  - 3.1.  $\{w \in \{0, 1\}^* : w \text{ has three consecutive 0's or three consecutive 1's or both}\}$ . [7 points]
  - 3.2.  $\{w \in \{0, 1\}^* : w \text{ has three consecutive 0's and three consecutive 1's}\}$ . [7 points]
  - 3.3. The set of strings in  $\{0, 1\}^*$  with an equal number of 0's and 1's such that no prefix has two more 0's than 1's nor two more 1's than 0's. [10 points]
  - 3.4. Let us define a valid floating point number as  $u.v$ , where  $u$  and  $v$  are (finite) strings of decimal digits (0..9) satisfying the following constraints: (the symbol "." between  $u$  and  $v$  is the decimal point.)
    - i. Neither  $u$  nor  $v$  may be  $\varepsilon$ .
    - ii.  $u$  can be just 0. If  $u$  is not 0,  $u$  has no leading 0's.
    - iii.  $v$  can be just 0. If  $v$  is not 0,  $v$  has no trailing 0's.(Thus, for example, 0.0, 231.0 and 5.608 are valid, but 0.00, 05.68, .65, 12. and 4.5100 are not valid.)  
Give a regular expression for the set of valid floating point numbers described above. You might want to introduce some notation first to keep your expression small and readable. [10 points]

4. Let  $L$  be a nonempty language and  $M$  an NFA that recognizes  $L$ . Prove that  $M$  can be converted into an NFA  $M'$  which recognizes the same language  $L$  and has exactly one accept state. Your proof *must* describe  $M'$  both informally, using plain English, *and* formally, using mathematical notation. [10 points]
5. For a language  $L$  over alphabet  $\Sigma$ , define  $\text{HALF}(L) = \{x \in \Sigma^* : \exists y \in \Sigma^* (|x| = |y| \text{ and } xy \in L)\}$ . Prove that if  $L$  is regular, then so is  $\text{HALF}(L)$ . Your proof *must* be formal; proofs not written in a formal mathematical style get very little credit even if they express the right intuition. [16 points]

Hint: Approach 1: Build an NFA. Nondeterministically guess which state the DFA for  $L$  will end up in after reading  $x$  and nondeterministically guess a  $y$  to append to  $x$ . Approach 2: Build a DFA. Work forwards and backwards simultaneously and try to meet in the middle.

### Challenge Problems

Remember that challenge problems carry no regular credit, but are intended to provide a higher level of challenge for those who want to think further about the theory of computing.

**CP1:** For the language  $L$  from Problem 1, prove that it is impossible to design a DFA with 5 or fewer states.

**CP2:** For a language  $L$  over alphabet  $\Sigma$ , define  $\text{LOG}(L) = \{x \in \Sigma^* : \exists y \in \Sigma^* (|y| = 2^{|x|} \text{ and } xy \in L)\}$ . Prove that if  $L$  is regular, then so is  $\text{LOG}(L)$ .
